

Here are examples for each AVL tree balancing case:

## 1. Left-Left Imbalance (Single Rotation)

**Example:**

- Start with a balanced tree: 10 as root, 5 as left child, 15 as right child
- Insert 3 as left child of 5
- Insert 1 as left child of 3
- Now the tree is imbalanced with left side too heavy (height difference of 2)

**Before rotation:**

```
  10
 /  \
5    15
/
3
/
1
```

**After single right rotation:**

```
  5
 / \
3  10
/  \
1   15
```

## 2. Left-Right Imbalance (Double Rotation)

**Example:**

- Start with: 20 as root, 10 as left child, 30 as right child
- Insert 15 as right child of 10
- Now node 20 has a left-right imbalance

**Before rotations:**

```
  20
 /  \
10  30
```

\  
15

**After left rotation on 10, then right rotation on 20:**

15  
/ \  
10 20  
    \  
      30

### 3. Right-Left Imbalance (Double Rotation)

**Example:**

- Start with: 20 as root, 10 as left child, 30 as right child
- Insert 25 as left child of 30
- Now node 20 has a right-left imbalance

**Before rotations:**

20  
/ \  
10 30  
    /  
   25

**After right rotation on 30, then left rotation on 20:**

25  
/ \  
20 30  
/  
10

### 4. Right-Right Imbalance (Single Rotation)

**Example:**

- Start with a balanced tree: 10 as root, 5 as left child, 15 as right child

- Insert 20 as right child of 15
- Insert 25 as right child of 20
- Now the tree is imbalanced with right side too heavy

**Before rotation:**

**After single left rotation:**

## Practical Applications:

Each of these rotations is triggered by specific insertion or deletion operations:

- **Left-Left Case:** Often happens when inserting a sequence of decreasing values into an initially empty tree (like 50, 40, 30...)
- **Right-Right Case:** Often happens when inserting a sequence of increasing values (like 10, 20, 30...)
- **Left-Right Case:** Can occur when inserting values that zigzag (like 50, 30, 40)
- **Right-Left Case:** Can occur when inserting values that zigzag in the opposite direction (like 10, 30, 20)

These rotations ensure the tree remains balanced so that operations maintain  $O(\log n)$  time complexity rather than degrading to  $O(n)$ .
